# Class 8: Partial pooling and zero-inflation

Andrew Parnell andrew.parnell@mu.ie

### Learning outcomes:

- ▶ Be able to fit some basic zero inflation and hurdle models
- ▶ Be able to understand and fit some multinomial modelling examples

#### Zero-inflation and hurdle models

Let's introduce some new data. This is data from an experiment on whiteflies:

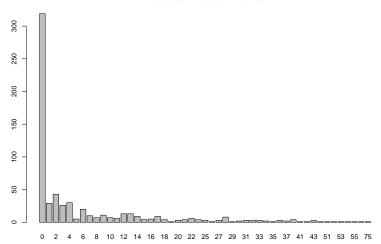

```
wf = read.csv('../data/whitefly.csv')
head(wf)
```

```
##
    imm week block trt n live plantid
## 1
    15
          1
               3
                  5 12
                        11
## 2 16
         2
               3 5 8 6
## 3 28
         3
               3 5 10 10
   17 4
                  5 10 8
## 4
          5
               3 5 10
                        10
## 5
## 6
    28
          6
               3
                  5 10
                        10
```

The response variable here is the count imm of immature whiteflies, and the explanatory variables are block (plant number), week, and treatment treat.

### Look at those zeros!

#### Number of immature whiteflies

#### A first model

- ▶ These are count data so a Poisson distribution is a good start
- Let's consider a basic Poisson distribution model for Y<sub>i</sub>, i = 1,..., N observations:

$$Y_i \sim Po(\lambda_i)$$

$$\log(\lambda_i) = \beta_{\mathsf{trt}_i}$$

We'll only consider the treatment effect but we could run much more complicated models with e.g. other covariates and interactions

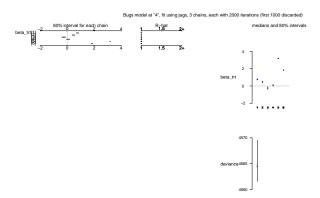

# Fitting the model in JAGS

```
model_code = '
model
  # Likelihood
  for (i in 1:N) {
    y[i] ~ dpois(lambda[i])
    log(lambda[i]) <- beta trt[trt[i]]</pre>
  # Priors
  for (j in 1:N_trt) {
    beta_trt[j] ~ dnorm(0, 100^-2)
```

# Running the model

#### Results

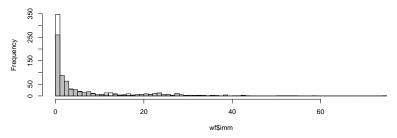

### plot(jags\_run)

Some clear treatment effects - treatment  ${\bf 5}$  in particular

### Did the model actually fit well?

#### Histogram of wf\$imm

#### What about the zeros?

One way of broadening the distribution is through over-dispersion which we have already met:

$$\log(\lambda_i) \sim N(\beta_{\mathsf{trt}_i}, \sigma^2)$$

- ▶ However this doesn't really solve the problem of excess zeros
- ▶ Instead there are a specific class of models called *zero-inflation* models which use a specific probability distribution. The zero-inflated Poisson (ZIP) with ZI parameter  $q_0$  is written as:

$$p(y|\lambda) = \begin{cases} q_0 + (1 - q_0) \times Poisson(0, \lambda) & \text{if } y = 0\\ (1 - q_0) \times Poisson(y, \lambda) & \text{if } y \neq 0 \end{cases}$$

# Fitting models with custom probability distributions

- ▶ The Zero-inflated Poisson distribution is not included in Stan or JAGS by default. We have to create it
- ▶ It's possible to create new probability distributions in Stan
- It's a little bit fiddly to do so in JAGS, we have to use some tricks
- We will use JAGS to create a mixture of Poisson distributions; A Poisson(0) distribution for the zeros, and a Poisson( $\lambda$ ) distribution for the rest

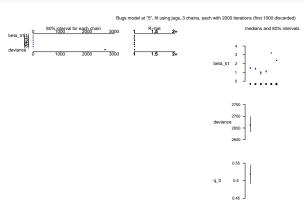

# Fitting the ZIP in JAGS

```
model_code =
model
  # Likelihood
  for (i in 1:N) {
    y[i] ~ dpois(lambda[i] * z[i] + 0.0001)
    log(lambda[i]) <- beta trt[trt[i]]</pre>
    z[i] \sim dbinom(q 0, 1)
  # Priors
  for (j in 1:N trt) {
    beta trt[j] ~ dnorm(0, 100^-2)
  q 0 \sim dunif(0, 1)
```

# Running the model

### Results

### plot(jags\_run)

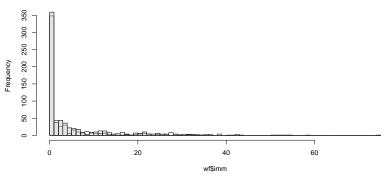

# Did it work any better? - code

```
beta_means = jags_run$BUGSoutput$mean$beta_trt
q_0_mean = jags_run$BUGSoutput$mean$q_0[1]
y_sim_mean = exp(beta_means[wf$trt])
rZIP = function(mean, q_0) {
   pois = rpois(length(mean), mean)
   pois[runif(length(mean)) < q_0] = 0
   return(pois)
}
y_sim = rZIP(y_sim_mean, q_0_mean)</pre>
```

# Did it work any better? - picture

```
hist(wf$imm, breaks = seq(0,max(wf$imm)))
hist(y_sim, breaks = seq(0,max(wf$imm)),
    add = TRUE, col = rgb(0.75,0.75,0.75,0.4))
```

#### Histogram of wf\$imm

#### Some more notes on Zero-inflated Poisson

- ▶ This model seems to predict the number of zeros pretty well. It would also be interesting to perhaps try having a different probability of zeros  $(q_0)$  for different treatments
- ▶ It might be that the other covariates explain some of the zero behaviour
- We could further add in both zero-inflation and over-dispersion

#### An alternative: hurdle models

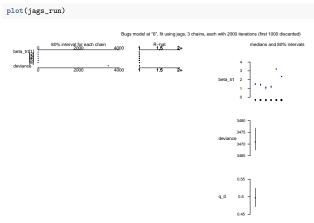

- ▶ ZI models work by having a parameter (here  $q_0$ ) which is the probability of getting a zero, and so the probability of getting a Poisson value (which could also be a zero) is 1 minus this value
- An alternative (which is slightly more complicated) is a hurdle model where  $q_0$  represents the probability of the *only way* of getting a zero. With probability  $(1-q_0)$  we end up with a special Poisson random variable which has to take values 1 or more
- ► In some ways this is richer than a ZI model since zeros can be deflated or inflated
- This is a bit fiddlier to fit in JAGS

### A hurdle-Poisson model in JAGS

```
model_code = '
model
  # Likelihood
  for (i in 1:N) {
    y[i] ~ dpois(lambda[i])T(1,)
    log(lambda[i]) <- beta_trt[trt[i]]</pre>
  for(i in 1:N_0) {
    y 0[i] ~ dbin(q 0, 1)
  # Priors
  for (j in 1:N trt) {
    beta trt[j] ~ dnorm(0, 100^-2)
  }
  q 0 \sim dunif(0, 1)
```

# Running the model

### Results

### Some final notes on ZI models

- ➤ To complete the Poisson-Hurdle fit we would need to simulate from a truncated Poisson model. This starts to get very fiddly though see the jags\_examples repository for worked examples
- We can extend these models further by using a better count distribution such as the negative binomial which has an extra over-dispersion parameter
- We can also add covariates into the zero-inflation component, though it is not always clear whether this is desirable

#### The multinomial distribution

- Multinomial data can be thought of as multivariate discrete data
- It's usually used in two different scenarios:
  - 1. For classification, when you have an observation falling into a single one of K possible categories
  - 2. For multinomial regression, where you have a set of counts which sum to a known value N
- We will just consider the multinomial regression case, whereby we have observations  $y_i = [y_{i1}, \dots, y_{iK}]$  where the sum  $\sum_{k=1}^{K} y_{ik} = N_i$  is fixed
- The classification version is a simplification of the regression version

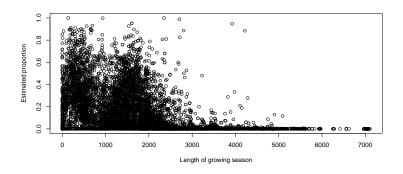

### Some new data! - pollen

```
pollen = read.csv('../data/pollen.csv')
head(pollen)
     GDD5 MTCO Abies Alnus Betula Picea Pinus.D Quercus.D Gramineae
## 1 1874 -7.9
                        50

                                             673
```

These data are pollen counts of 7 varieties of pollen from modern samples with two covariates

### Some plots

- ► The two covariates represent the length of the growing season (GDD5) and harshness of the winter (MTCO)
- ► The task is to find which climate regimes each pollen variety favours

#### A multinomial model

▶ The multinomial distribution is often written as:

$$[y_{i1},\ldots,y_{iK}] \sim Mult(S_i,\{p_{i1},\ldots,p_{iK}\})$$

or, for short:

$$y_i \sim Mult(S_i, p_i)$$

- ► The key parameters here are the probability vectors p<sub>i</sub>. It's these we want to use a link function on to include the covariates
- We need to be careful as each must sum to one:  $\sum_{k=1}^{K} p_{ik} = 1$ . Any link function must satisfy this constraint

# Prior distributions on probability vectors

- When K = 2 we're back the binomial-logit we met in the first day, and we can use the logit link function
- When K > 2 a common function to use is the *soft-max* function:

$$p_{ik} = \frac{\exp(z_{ik})}{\sum_{j=1}^{K} \exp(z_{ij})}$$

- This is a generalisation of the logit function
- The next layer of our model sets, e.g.:

$$z_{ik} = \beta_0 + \beta_1 GDD5_i + \gamma_2 MTCO_i + \dots$$

### JAGS code

```
model_code = '
model
  # Likelihood
  for (i in 1:N) { # Observation loops
    y[i,] ~ dmulti(p[i,], S[i])
    for(j in 1:M) { # Category loop
      \exp_z[i,j] \leftarrow \exp(z[i,j])
      p[i,j] \leftarrow \exp z[i,j]/\sup(\exp z[i,j])
      z[i,j] <- beta[j,]%*%x[i,]
  # Prior
  for(j in 1:M) {
    for(k in 1:K) {
      beta[j,k] ~ dnorm(0, 0.1^-2)
```

# Let's fit it (first 500 obs only)

```
model_data = list(N = nrow(pollen[1:500,]),
                  y = pollen[1:500,3:9],
                  x = cbind(1, scale(cbind(pollen[1:500,1:
                                            pollen[1:500,1:5
                  S = pollen[1:500,10],
                  K = 5, # Number of covars
                  M = 7) # Number of categories
# Run the model
model_run = jags(data = model_data,
                 parameters.to.save = c("p"),
                 model.file = textConnection(model code))
```

### Results 1

#### plot(model\_run)

Bugs model at "7", fit using jags, 3 chains, each with 2000 iterations (first 1000 discarded)

	80% interval f	or each chain			R-hat	
242100	242200	242300	242400	- 1	1.5	2+
deviance				-		
242100	242200	242300	242400	1	1.5	2+

medians and 80% intervals

### Results 2

#### Notes about this model

- ► This model is not going to fit very well, since it is unlikely that a linear relationship between the covariates and the pollen counts will match the data
- ▶ It might be better to use e.g. a spline model (not covered in this course, but we can talk about it)
- Similarly we might need some complex interactions between the covariates as they are strongly linked
- We have constrained the parameters here so that the slopes and intercepts borrow strength across species. Does this make sense? What else could we do?

#### Some final notes about multinomial models

- These models can be a pain to deal with as there are tricky constraints on the  $\beta$  parameters to make them all sum to 1. Instead it's often easier to just put a tight prior distribution on them, e.g.  $\beta \sim N(0,0.1)$
- ► The softmax function is one choice but there are lots of others (logistic ratios, the Dirichlet distribution, ...)
- Whilst the classification version of this model just has binary  $y_i$  (with just a single 1 in it, i.e.  $S_i = 1$ ) most packages (including JAGS and Stan) have a special distribution (e.g. dcat in JAGS) for this situation

# Summary

- We have fitted some zero inflated and hurdle Poisson models in JAGS
- ▶ We have seen a simple multinomial logistic regression
